**ABSTRACT**

Estrogen-related receptor  $\gamma$  (ERR $\gamma$ ) is a major positive regulator of hepatic gluconeogenesis. Its transcriptional activity is suppressed by phosphorylation signaled by insulin in the fed state, but whether post-translational modification (PTM) alters its gluconeogenic activity in the fasted state is not known. Metabolically active hepatocytes direct a small amount of glucose into the hexosamine biosynthetic pathway (HBP) leading to protein *O*-GlcNAcylation. Here we demonstrate that ERR $\gamma$  is *O*-GlcNAcylated by *O*-GlcNAc transferase (OGT) in the fasted state. This stabilizes the protein by inhibiting proteasome mediated protein degradation, increasing ERR $\gamma$  recruitment to gluconeogenic gene promoters. Mass spectrometry identifies two serine residues (S317, S319) present in the ERR $\gamma$  ligand binding domain (LBD) that are *O*-GlcNAcylated. Mutation of these residues destabilizes ERR $\gamma$  protein, and blocks the ability of ERR $\gamma$  to induce gluconeogenesis *in vivo*. The impact of this pathway on gluconeogenesis *in vivo* was confirmed by the observation that decreasing the amount of *O*-GlcNAcylated ERR $\gamma$  by overexpressing the deglycosylating enzyme *O*-GlcNAcase (OGA) decreases ERR $\gamma$  dependent glucose production in fasted mice. We conclude that *O*-GlcNAcylation of ERR $\gamma$  serves as a major signal to promote hepatic gluconeogenesis.

## INTRODUCTION

*O*-GlcNAcylation works as a nutrient sensor in the liver to maintain energy homeostasis in response to varying nutrient flux [1]. *O*-GlcNAcylation is extensively linked with glucose metabolism in liver. L-glutamine fructose-6-phosphate amidotransferase (GFAT) overexpression leads to peripheral insulin resistance [2], [3]. Transgenic mice overexpressing OGT in skeletal muscle and fat exhibit elevated circulating insulin levels and insulin resistance [4]. IRS1/IRS2 of insulin signaling is *O*-GlcNAcylated [5], and *O*-GlcNAcylation has been shown to be a negative regulator of insulin signaling [6]. *O*-GlcNAcylation of FOXO1, CRTC2 and PGC-1 $\alpha$  modulates expression of gluconeogenic genes [7], [8], [9], [10]. Chronic increase in *O*-GlcNAcylation levels of PDX1 and NeuroD1 may contribute to hyperinsulinemia in Type 2 diabetes [11], [12]. Thus, by being intimately intertwined with metabolism, HBP and its end product *O*-GlcNAc link transcriptional processes to cellular glucose metabolism and insulin resistance.

Estrogen-related receptors (ERRs) are members of the NR3B subfamily of nuclear receptors, which include ERR $\alpha$ , ERR $\beta$  and ERR $\gamma$ . ERR $\gamma$  is primarily expressed in heart, brain, kidney, pancreas and liver tissues and is induced during fasting in murine liver [13], [14], [15]. ERR $\gamma$  plays an important role in the regulation of glucose, lipid, alcohol and iron metabolism in mouse liver [16], [17]. Hepatic ERR $\gamma$  expression is induced in fasting and the diabetic state, and causes insulin resistance and glucose intolerance [18]. Induction of hepatic ERR $\gamma$  impairs insulin signaling through diacylglycerol-mediated protein kinase  $\epsilon$  activation [19], suggesting that ERR $\gamma$  transcriptional activity could be involved in insulin action to maintain glucose homeostasis. Recently our laboratory reported that insulin-dependent phosphorylation of ERR $\gamma$  alters its transcriptional activity to suppress hepatic gluconeogenesis in the fed state [20].

PGC-1 $\alpha$  is a transcriptional co-activator involved in hepatic glucose metabolism. Fasting induces hepatic PGC-1 $\alpha$  expression that directly interacts with transcription factors including HNF4 $\alpha$ , FOXO1, and GR to increase the expression of gluconeogenic genes [21] [22]. PGC-1 $\alpha$  overexpression leads to increased expression of G6Pase and PEPCK, key enzymes in the hepatic gluconeogenesis. Conversely, knockdown or knockout of PGC-1 $\alpha$  results in lower blood glucose levels as a result of reduced gluconeogenesis.

As insulin-dependent PTM regulates the transcriptional activity of ERR $\gamma$  in the fed state, herein we investigated whether fasting-dependent activation of the transcriptional activity of ERR $\gamma$  involves *O*-GlcNAcylation. We demonstrate that the fasting condition triggers *O*-GlcNAcylation of ERR $\gamma$  that results in protein stabilization. *O*-GlcNAcylation of ERR $\gamma$  by OGT decreases its ubiquitination (Ub), and cooperatively upregulates gluconeogenesis. In contrast, the fed condition decreases *O*-GlcNAcylation of ERR $\gamma$ , resulting in ubiquitin-mediated protein degradation. Overall, our study describes how *O*-GlcNAcylation modulates gluconeogenesis via ERR $\gamma$ .

## RESEARCH DESIGN AND METHODS

### Animal Experiments

Male 8-week-old C57BL/6J mice, maintained at the Korea Research Institute of Bioscience and Biotechnology (KRIBB) were fed either a high fat diet (HFD) (D12492; Research Diets, New Brunswick, NJ) or a normal chow diet for 12 weeks. At the end of 12 weeks mice were sacrificed and liver tissue was utilized for identification of *O*-GlcNAcylation of  $ERR\gamma$ . *ob/ob* and *db/db* mice (7–12 weeks old; Charles River Laboratories) were maintained at KRIBB in an animal facility with *ad libitum* access to water and a standard laboratory diet. Liver tissue was utilized for identification of *O*-GlcNAcylation of  $ERR\gamma$ . Male 7-week old C57BL/6J mice (The Jackson Laboratory, Bar Harbor, Maine, USA) were obtained from Ochang Branch Institute, KRIBB. After two weeks, adenoviruses (Ad-GFP, Ad-wt  $ERR\gamma$  and Ad-Ser317Ala+Ser319Ala  $ERR\gamma$ ;  $5.9 \times 10^9$  plaque-forming units/mouse) were delivered by tail-vein injection into mice. Glucose tolerance test was performed at day 5 after a tail-vein injection of adenoviruses. Briefly, mice fasted 16 h were injected intraperitoneally with 1 g/kg glucose, and blood glucose was measured in tail-vein blood using a blood glucose meter and test strips (Accu-Chek Aviva meter system; Roche Diagnostics, Indianapolis, IN, USA). All mice were acclimatized to a 12 h light-dark cycle at  $22 \pm 2^\circ\text{C}$  with free access to food and water in a specific pathogen-free facility. All animal experiments were approved and performed by the Institutional Animal Care and Use Committee of KRIBB.

### Glucose Output Assay

Glucose production from primary mouse hepatocytes was measured using a colorimetric glucose oxidase assay kit according to the manufacturer's protocol. Briefly, after the

experimental time period as indicated, the cells were washed three times with phosphate-buffered saline. Then the cells were incubated for 3 h at 37 °C, 5% CO<sub>2</sub>, in glucose production buffer (glucose-free DMEM, pH 7.4, containing 20 mmol/liter sodium lactate, 1 mmol/liter sodium pyruvate, and 15 mmol/liter HEPES, without phenol red), and the glucose assays were performed.

### **Glucagon Assay**

Blood glucagon levels were measured using mouse glucagon EIA kit (Ray Biotech, Inc.) following manufacturer's protocol.

### **Cell culture and reagents**

Primary hepatocytes were isolated from C57BL/6J mice (male, 20-30 g) by collagenase perfusion [23] and seeded with Medium 199 (Cellgro). After 3–6 h of attachment, cells were infected with the indicated adenoviruses for overexpression or treated with various chemicals as indicated. HEK 293T and AML12 cells were maintained as described previously [24]. Transient transfection was performed using Lipofectamine 2000 (Invitrogen) or SuperFect (Qiagen, Hilden, Germany) according to the manufacturers' instructions.  $\beta$ -N-Acetyl-D-glucosamine (GlcN), 6-diazo-5-oxo-L-norleucine (DON), glucagon, insulin, cycloheximide (CHX), ANTI-FLAG M2 affinity gel, glucose oxidase assay kit and streptozotocin (STZ) were purchased from SIGMA. MG-132 protease inhibitors were purchased from Calbiochem. Express Protein Labeling Mix [<sup>35</sup>S] (NEG072002MC) was purchased from Perkin Elmer. Mouse Glucagon EIA kit (EIAM-GLU) was purchased from Ray Biotech, Inc. Antibodies were purchased as follows : O-GlcNAc from Covance,  $\alpha$ -tubulin from Abfrontier, ERR $\gamma$  from Perseus Proteomix, OGT from

Abcam, FLAG, Anti-FLAG M2 and HA from Cell Signaling, and G6Pase, Mdm2, ubiquitin, Gal4, PGC-1 $\alpha$  and PEPCK from Santa Cruz Biotechnology.

### **Plasmid and adenovirus vector constructs**

Expression vectors for HA-ERR $\gamma$ , FLAG-ERR $\gamma$ , HA-PGC-1 $\alpha$  and Sft4-luc containing three copies of the ERR $\gamma$  binding site were described previously [25]. HA-ERR $\alpha$  was described previously [26]. FLAG-human OGT was constructed by inserting the full PCR fragment of the open reading frame into the Not1/Sal1 sites of the p3XFLAG-CMV-7.1 vector. FLAG-human OGA was constructed by inserting the full PCR fragment of the open reading frame into the Bgl2/Sal1 sites of the pFLAG-CMV-7.1 vector. FLAG-mutant ERR $\gamma$ 's (Ser317Ala, Ser319Ala, Ser317Ala+Ser319Ala) were constructed using wild-type ERR $\gamma$  as template by Quick Change Lightning Site-Directed Mutagenesis kit from Agilent Technologies. Gal4-DBD and Gal4-tk-Luc were described previously [27]. Briefly, Gal4-ERR $\gamma$ -LBD is a fusion protein consisting of the Gal4 DNA binding domain (Gal4-DBD; amino acids 1–147) and ERR $\gamma$  ligand binding domain (ERR $\gamma$ -LBD; amino acids 189–458). This fusion protein activates transcription of a reporter construct (Gal4-tk-luc) containing five GAL4 binding sites (upstream activator sequence) upstream of the firefly luciferase gene in the pGL2-Promoter. Gal4-DBD-Ser317Ala ERR $\gamma$ , Gal4-DBD-Ser319Ala ERR $\gamma$ , and Gal4-DBD-Ser317Ala+Ser319Ala ERR $\gamma$  were constructed using Gal4-DBD-wild-type ERR $\gamma$  as template by Quick Change Lightning Site-Directed Mutagenesis kit from Agilent Technologies. wtPEPCK-luc, and ERRE mutant PEPCK-luc were described previously [28]. Adenoviruses expressing unspecific (US) shRNA, shERR $\gamma$ , control GFP, and ERR $\gamma$  were described previously [28]. Adenovirus OGT (Ad-OGT) encoding human OGT gene, adenovirus OGA (Ad-OGA) encoding human OGA gene, and adenovirus

Ser317Ala+Ser319Ala ERR $\gamma$  (Ad-Ser317Ala+Ser319Ala ERR $\gamma$ ) were generated with the pAd-easy system as described previously [29]. All viruses were purified by using CsCl gradient protocol.

### **Hepatic FLAG-ERR $\gamma$ complex purification and mapping of *O*-GlcNAc site using mass spectrometry**

Overexpressed wild-type FLAG-ERR $\gamma$  proteins from mouse liver were purified using FLAG-M2 agarose and subjected to SDS-PAGE. Purified protein was digested with trypsin (Promega, Madison, WI) (25 ng/ $\mu$ l) for 16 h at 37°C. After in gel digestion, tryptic peptides were separated by online reversed-phase chromatography using a Thermo Scientific Eazy nano LC II autosampler with a reversed-phase peptide trap EASY-Column (100  $\mu$ m inner diameter, 2 cm length) and a reversed-phase analytical EASY-Column (75  $\mu$ m inner diameter, 10 cm length, 3  $\mu$ m particle size, both Thermo Scientific). Electrospray ionization was performed using a 30  $\mu$ m (i.d.) nano-bore stainless steel online emitter (Thermo Scientific) and a voltage set at 2.6 V., at a flow rate of 300 nl/min. The chromatography system was coupled on-line with an LTQ Velos Orbitrap mass spectrometer. Protein identification was accomplished utilizing the Proteome Discoverer v1.3 database search engine (Thermo scientific) and searches were performed against IPI.Humanv3.87 FASTA database or ERR $\gamma$  FASTA database. A fragment mass tolerance of 1.2 Da, peptide mass tolerance of 25 ppm, and maximum missed cleavage of 2 were set.

### **Real time quantitative RT-PCR (qPCR) analysis**

Total RNA was isolated using Trizol reagent, cDNA was synthesized using a reverse transcriptase kit (Intron Biotechnology, Inc.), and qPCR was performed with SYBR green PCR kit (Enzynomics). The amount of mRNA for each gene was normalized to that of actin mRNA.

### **ChIP assay**

Nuclear isolation of primary hepatocytes and cross-linking of protein to DNA were performed as described previously [28]. After sonication, soluble chromatin was subjected to immunoprecipitation using anti-ERR $\gamma$  antibody. DNA was recovered by phenol/chloroform extraction and analyzed by PCR using primers against relevant promoters. Primer sequences: mouse PEPCK1 promoter forward: 5'- CTAGCCAGCTTTGCCTGACT-3' and reverse: 5'-GGGTCCCCACGACCTTCCA A -3'.

### **Western Blot Analysis**

Whole cell extracts were prepared using RIPA buffer (50 mM Tris at pH 7.5, 150 mM NaCl, 1% NP-40, 5mM EDTA). Proteins from whole cell lysates were separated by 10% SDS-PAGE and then transferred to nitrocellulose membranes. The membranes were probed with different antibodies. Immunoreactive proteins were visualized using an Amersham Biosciences ECL kit (GE Healthcare) according to the manufacturer's instructions.

### **In Vivo Imaging**

C57BL/6J mice were infected with respective viruses via tail vein injections. Four days post injection, mice were fasted for 16 h and imaged using an IVIS Lumina II imaging system (Caliper Life Sciences, Hopkinton, MA, USA) as described previously [28].

### **Confocal Microscopy**

At 24 h after transfection, the cells were fixed with 2% formaldehyde, immunostained and subjected to observation by confocal microscopy using a laser-scanning confocal microscope (Olympus Corp., Lake Success, NY).

### **Pulse-chase experiment**

AML12 cells were transfected with FLAG-wt ERR $\gamma$ , FLAG-S317A ERR $\gamma$ , FLAG-S319A ERR $\gamma$  and FLAG-S317A+S319A ERR $\gamma$  and incubated in methionine and cystine-free medium for 2 h. Trans-label mixture (Perkin Elmer) containing <sup>35</sup>S-methionine was added for 30 min and then cells were cultured in normal medium up to 3 h. FLAG-ERR $\gamma$  was immunoprecipitated with M2 antibody in RIPA buffer and radioactive FLAG-ERR $\gamma$  was detected by autoradiography.

### **Statistical Analyses**

All values are expressed as means  $\pm$  s.e.m. The significance between mean values was evaluated by two-tailed Student's *t* test.

## RESULTS

### **ERR $\gamma$ is modified by *O*-GlcNAc**

ERR $\gamma$  is a key positive regulator of hepatic gluconeogenesis [28]. ERR $\gamma$  phosphorylation by PKB/Akt also contributes to insulin-mediated inhibition of hepatic gluconeogenesis [20]. Many factors that regulate hepatic gluconeogenesis are *O*-GlcNAcylated in various conditions [30], [7], [31]. Hence we sought to determine whether ERR $\gamma$  is modified by *O*-GlcNAc. HBP intermediate GlcN treatment significantly increased ERR $\gamma$  *O*-GlcNAcylation levels as well as ERR $\gamma$  protein content in a dose dependent manner (Figure 1A). Consistent with a rise in ERR $\gamma$  protein levels, GlcN treatment significantly reduced ERR $\gamma$  ubiquitination levels and increased ERR $\gamma$  transcriptional activity (Supplementary figure 1A-B). Glucose (Glc) flux through HBP regulates *O*-GlcNAcylation [1]. Therefore, to determine whether glucose could directly affect *O*-GlcNAcylation of ERR $\gamma$ , mouse primary hepatocytes (MPH) were treated with 5 and 25 mM glucose. High glucose significantly increased *O*-GlcNAcylation of ERR $\gamma$  along with ERR $\gamma$  protein levels (Figure 1B). This was further confirmed when OGT co-transfection markedly enhanced *O*-GlcNAcylation of ERR $\gamma$  (Figure 1C). Since ERR $\alpha$  and ERR $\gamma$  are both associated with hepatic glucose metabolism, we also examined whether OGT overexpression could lead to ERR $\alpha$  *O*-GlcNAcylation. Unlike ERR $\gamma$ , *O*-GlcNAcylation was not detected for ERR $\alpha$  (Figure 1D).

*O*-GlcNAcylation is linked with protein stability [30], [31], [32], [33]. From our results (Figure 1A-B), we speculated that *O*-GlcNAcylation could stabilize ERR $\gamma$  by decreasing protein degradation. To test this, HEK 293T cells were co-transfected with ERR $\gamma$  and OGA or OGT expression vectors followed by MG-132 treatment to inhibit proteasome-mediated protein

degradation. ERR $\gamma$  ubiquitination levels were significantly raised and *O*-GlcNAcylation levels were decreased in presence of OGA, whereas OGT had an entirely opposite effect, suggesting that OGT triggers ERR $\gamma$  *O*-GlcNAcylation that inhibits ERR $\gamma$  ubiquitination and stabilizes it (Figure 1E). Next, to examine the functional implications of *O*-GlcNAcylation, reporter gene assay with transient transfection was carried out in the 293T cell line. ERR $\gamma$  significantly enhanced the Sft4-luc reporter activity which was further augmented in presence of OGT. OGA had an inverse effect to that of OGT and significantly reduced ERR $\gamma$  transcriptional activity. However, ERR $\alpha$  could not markedly activate the reporter gene even in presence of OGT (Figure 1F). Activation of the Gal4-tk-luc reporter gene by Gal4-ERR $\gamma$ -LBD was significantly augmented by OGT, whereas OGA significantly repressed it, indicating that *O*-GlcNAcylation of ERR $\gamma$  might occur in its LBD (Figure 1G). Overall, these results suggest that ERR $\gamma$  is subject to *O*-GlcNAcylation which in turn increases protein stability by decreasing ubiquitin mediated protein degradation and also enhances ERR $\gamma$  transcriptional activity.

### **Glucagon increases *O*-GlcNAcylation of ERR $\gamma$**

Hepatic ERR $\gamma$  expression is increased by fasting-dependent activation of the CREB-CRTC2 pathway [28], [18]. Hence we sought to determine whether fasting-dependent increase in ERR $\gamma$  expression is associated with *O*-GlcNAcylation. Fasting significantly enhanced *O*-GlcNAcylation of ERR $\gamma$  compared to the fed state. This stands in contrast to ERR $\gamma$  ubiquitination levels which were higher in the fed condition than the fasting condition, suggesting that *O*-GlcNAcylation mediates ERR $\gamma$  stability in the fasting condition (Figure 2A). To confirm that *O*-GlcNAcylation mediates ERR $\gamma$  stability in the fasting condition, we overexpressed OGA in this condition. Overexpression of OGA significantly reduced *O*-

GlcNAcylation of  $ERR\gamma$  and simultaneously increased ubiquitination of  $ERR\gamma$ , resulting in lowering of  $ERR\gamma$  abundance, unambiguously establishing that  $ERR\gamma$  stability is governed by *O*-GlcNAcylation in the fasting condition (Figure 2B). Increased protein stability is associated with decreased interaction between protein and E3 ubiquitin-ligases such as Mdm2 [32]. We observed that fasting increased OGT- $ERR\gamma$  interactions in a time dependent manner, resulting in enhanced *O*-GlcNAcylation and reduced Mdm2- $ERR\gamma$  interactions in mice (Figure 2C). The binding of OGT and  $ERR\gamma$  was reduced, but the levels of  $ERR\gamma$  *O*-GlcNAcylation were still intensified after 3 h of fasting (Figure 2C). To clarify this, we tested whether the interactions between  $ERR\gamma$  and OGT or OGA might be dynamically altered during the fasting period. The interaction between  $ERR\gamma$  and OGT increased in a fasting time manner, reaching a peak between 3-6 h and then declining, whereas the interaction between  $ERR\gamma$  and OGA decreased in a fasting time manner (Supplementary figure 1C), suggesting that in the fed state OGA interacts with  $ERR\gamma$  and destabilizes it, whereas in the fasting condition OGT interacts with  $ERR\gamma$  and stabilizes it. Interestingly, protein levels of both OGT and OGA were increased in the fasting (Supplementary figure 1C), which was supported by elevated OGT and OGA mRNA levels in fasting (Supplementary figure 1D). In spite of low circulating glucose, fasting promoted *O*-GlcNAcylation of  $ERR\gamma$ . Hence we speculate that glucagon could be more important than blood glucose for *O*-GlcNAcylation of  $ERR\gamma$  during fasting. To test this, we measured blood glucose and glucagon levels in a fasting time course experiment (Supplementary figure 1E-F). Blood glucose levels in fasting mice decreased from 0 to 12 h, whereas serum glucagon levels steadily increased from 0 h, reaching a peak at 6 h followed by a decrease at 12 h, though it remained significantly higher at 12 h than at 0 h.  $ERR\gamma$  *O*-GlcNAcylation levels gradually increased from 0 h, reaching a peak at 6 h and then remaining almost the same until 12 h, suggesting that

circulating glucagon levels are more important than circulating glucose levels for *O*-GlcNAcylation of ERR $\gamma$  during fasting.

Glucagon increases hepatic ERR $\gamma$  transcriptional activity during fasting [28]. Thus we sought to ascertain whether glucagon increases ERR $\gamma$  transcriptional activity by affecting *O*-GlcNAcylation. Glucagon treatment significantly increased ERR $\gamma$  *O*-GlcNAcylation levels resulting in higher protein stability through reduced ERR $\gamma$  ubiquitination (Figure 2D). As both high glucose (Figure 1B) and glucagon (Figure 2D) induced *O*-GlcNAcylation, we tested which is more important for *O*-GlcNAcylation of ERR $\gamma$ . Both high levels of glucose and glucagon increased ERR $\gamma$  *O*-GlcNAcylation levels and total protein levels. They have a cumulative effect when applied together (Supplementary figure 1G), but unlike glucagon, glucose did not increase ERR $\gamma$  mRNA levels (Supplementary figure 1H). The notion that *O*-GlcNAcylation mediates the effect of glucagon on ERR $\gamma$  protein stability was further corroborated when overexpression of OGA significantly reduced both *O*-GlcNAcylation and protein levels of ERR $\gamma$  (Figure 2E). Insulin induced by feeding suppresses ERR $\gamma$  transcriptional activity as well as gene expression [28], [20]. Thus we speculate that insulin may inhibit *O*-GlcNAcylation of ERR $\gamma$  leading to decreased protein stability. As we expected, glucagon induced ERR $\gamma$  *O*-GlcNAcylation was significantly suppressed by insulin treatment in AML12 cells. ERR $\gamma$  ubiquitination was markedly enhanced in presence of insulin compared to glucagon treatment resulting in lower protein stability (Figure 2F). Taken together, these results indicate that fasting increases *O*-GlcNAcylation of ERR $\gamma$  leading to protein stability, whereas feeding acts reciprocally to degrade ERR $\gamma$  by suppressing its *O*-GlcNAcylation.

### **ERR $\gamma$ is modified by *O*-GlcNAc at Ser317 and Ser319**

In order to identify the *O*-GlcNAc site of ERR $\gamma$  we infected mouse with Ad-FLAG-ERR $\gamma$  and extracted the ERR $\gamma$  protein from liver tissue through immunoprecipitation (Figure 3A-B). The mass spectrometry results show that Ser317 and Ser319 of ERR $\gamma$  are *O*-GlcNAcylated (Supplementary Figure 2-3). The primary structure of ERR $\gamma$  revealed that Ser317 and Ser319 were present in the LBD of ERR $\gamma$  (Figure 3C) which was consistent with the previous result that suggested *O*-GlcNAcylation site is in the LBD (Figure 1G). However, only Ser317 was conserved in ERR $\alpha$ , ERR $\beta$  and ERR $\gamma$  (Figure 3C). The three dimensional structure of ERR $\gamma$ -LBD provides a comprehensive view of the *O*-GlcNAcylation site. The two *O*-GlcNAcylated serine residues are located at the end of helix5 of the reported ERR $\gamma$ -LBD structures, which is locally stabilized with helix 6, helix 7 and a couple of strands. While Ser319 is completely exposed to the solvent accessible surface, Ser317 is partially hidden (Figure 3D). To verify the specific *O*-GlcNAcylation sites indicated by mass analysis, we constructed three site-specific point mutant cDNAs of ERR $\gamma$ , Ser317Ala ERR $\gamma$ , Ser319Ala ERR $\gamma$ , and Ser317Ala+Ser319Ala ERR $\gamma$ . The single mutants (Ser317Ala ERR $\gamma$  and Ser319Ala ERR $\gamma$ ) showed less *O*-GlcNAcylation compared to wild-type ERR $\gamma$ , whereas the double mutant (Ser317Ala+Ser319Ala) showed complete absence of an *O*-GlcNAc signal in the presence of GlcN (Figure 3E). Interestingly, even though the single mutants showed higher *O*-GlcNAcylation than the double mutant, all three mutants were highly ubiquitinated compared to wild-type in presence of GlcN, unambiguously suggesting that *O*-GlcNAcylation of both Ser317 and Ser319 is required for ERR $\gamma$  protein stability (Figure 3E). Consistent with these findings, we noticed that all three mutants showed significant lower stability compared to wild-type in pulse-chase experiment, demonstrating the importance of *O*-GlcNAcylation in ERR $\gamma$  protein stability

(Figure 3F). This was further confirmed when all three mutants showed significantly reduced protein levels in the presence of cycloheximide, a protein synthesis inhibitor (Supplementary figure 4A). Next, reporter gene assay revealed that unlike wild-type, the mutant ERR $\gamma$ 's had no significant transcriptional activity, suggesting that O-GlcNAcylation is required for ERR $\gamma$  transcriptional activity as well (Figure 3G). All three mutants were unable to bind to the PEPCK promoter revealing why they had no transcriptional activity (Figure 3H). Collectively, these results illustrate that O-GlcNAcylation stabilizes ERR $\gamma$  and increases its transcriptional activity.

### **O-GlcNAcylation affects ERR $\gamma$ -PGC-1 $\alpha$ interaction but not ERR $\gamma$ cellular localization**

Increase in transcriptional activity of transcription factors in response to O-GlcNAcylation was previously linked to their nuclear transport [7], [34]. Since the O-GlcNAcylation mutant ERR $\gamma$  had practically no transcriptional activity compared to wild-type (Figure 3G-H), we speculate that the O-GlcNAcylation mutant may not translocate into the nucleus. Unexpectedly, the Ser317Ala+Ser319Ala ERR $\gamma$  was located in the nucleus, indicating that sub-cellular localization of ERR $\gamma$  was not governed by O-GlcNAcylation (Figure 4A). Transcriptional co-activator PGC-1 $\alpha$  interacts with ERR $\gamma$  and is critical for ERR $\gamma$  transcriptional activity [28]. Hence, we examined whether PGC-1 $\alpha$  could interact with Ser317Ala+Ser319Ala ERR $\gamma$ . In AML12 cells, GlcN treatment significantly augmented O-GlcNAcylation of ERR $\gamma$  as well as ERR $\gamma$ -PGC-1 $\alpha$  interaction, whereas inhibiting HBP by treating with DON, an inhibitor of GFAT, the rate-limiting enzyme of HBP, significantly reduced O-GlcNAcylation of ERR $\gamma$  as well as ERR $\gamma$ -PGC-1 $\alpha$  interaction. We could not detect any interaction between ERR $\gamma$  Ser317Ala+Ser319Ala and PGC-1 $\alpha$ , supporting the idea that the HBP mediates ERR $\gamma$ -PGC-1 $\alpha$  interaction (Figure 4B). We also observed that GlcN treatment increased PGC-1 $\alpha$  protein levels

(Figure 4B), but not mRNA levels (Supplementary figure 4B). The rise in PGC-1 $\alpha$  protein levels could be due to the fact that *O*-GlcNAcylation also stabilizes PGC-1 $\alpha$  protein [30]. Next, STZ treatment, an inhibitor of OGA and promoter of *O*-GlcNAcylation [7], [35], significantly augmented PGC-1 $\alpha$ -ERR $\gamma$  interaction, demonstrating that OGA inhibition enhances *O*-GlcNAcylation of ERR $\gamma$  that results in substantial increase in PGC-1 $\alpha$ -ERR $\gamma$  interaction (Figure 4C). Along with ERR $\gamma$  (FLAG), PGC-1 $\alpha$  (HA) protein levels were also elevated in response to STZ treatment (Figure 4C), which is consistent with figure 4B where GlcN treatment elevated PGC-1 $\alpha$  protein levels. Next, we performed *in vitro* interaction study between PGC-1 $\alpha$  and Gal4 construct containing either wild-type or Ser317Ala+Ser319Ala ERR $\gamma$ -LBD as the LBD contains the *O*-GlcNAcylation site (Figure 3C). Similar to Gal4-wild-type ERR $\gamma$ -LBD, Gal4-Ser317Ala+Ser319Ala ERR $\gamma$ -LBD protein was as stable as the wild-type one, but we could not detect any interaction between PGC-1 $\alpha$  and Gal4-Ser317Ala+Ser319Ala ERR $\gamma$ -LBD, suggesting that *O*-GlcNAcylation in the LBD regulates ERR $\gamma$ -PGC-1 $\alpha$  interaction (Figure 4D). Similar to the double mutant, the two single mutants also could not interact with PGC-1 $\alpha$  (Supplementary figure 4C). Gal4-tk-Luc reporter gene assay revealed that Gal4-Ser317Ala+Ser319Ala ERR $\gamma$ -LBD was incapable of activating the reporter gene in the presence of PGC-1 $\alpha$  (Figure 4E). Moreover, Gal4-Ser317Ala+Ser319Ala ERR $\gamma$ -LBD was also unable to activate the reporter gene even in presence of GlcN or OGT (Supplementary figure 4D). Taken together, these results demonstrate that *O*-GlcNAcylation regulates ERR $\gamma$ -PGC-1 $\alpha$  interaction critical to ERR $\gamma$  transcriptional activity.

### ***O*-GlcNAcylation regulates ERR $\gamma$ mediated gluconeogenic gene expression**

HBP induces gluconeogenic enzymes gene expression through *O*-GlcNAcylation [7], [30]. ERR $\gamma$  is a key positive regulator of gluconeogenic enzymes gene expression [28], [18]. Our previous results described that ERR $\gamma$  was *O*-GlcNAcylated through HBP (Figure 1A, 4B-C). Therefore, to determine the contribution of *O*-GlcNAcylated ERR $\gamma$  in HBP induced gluconeogenesis in MPH, we knocked down endogenous ERR $\gamma$ . ERR $\gamma$  knockdown markedly reduced GlcN induced PEPCK and G6Pase protein levels (Figure 5A). OGT overexpression leads to induction of gluconeogenesis and OGT knockdown improves glucose homeostasis in diabetic mice [7], [30]. OGT overexpression significantly increased PEPCK and G6Pase mRNA levels, and this increase in mRNA levels was greatly suppressed by ERR $\gamma$  knockdown in MPH (Figure 5B, from left 1<sup>st</sup>/2<sup>nd</sup> panel). In line with PEPCK and G6Pase mRNA levels results, glucose production was also significantly reduced in response to ERR $\gamma$  knock down (Figure 5B, from left 4<sup>th</sup> panel). Effectiveness of OGT overexpression was confirmed by western blot analyses (Supplementary figure 4E). Next, to examine the effect of glucose or GlcN on gluconeogenic gene promoter activity, we used wild-type and ERRE mutant PEPCK promoter which is devoid of ERR $\gamma$  binding site. Exposure to glucose or GlcN increased wild-type promoter activity but this increase was greatly reduced with the ERRE mutant PEPCK promoter (Figure 5C). In a parallel approach, 293T cells were transfected with wild-type PEPCK promoter along with wild-type and Ser317Ala+Ser319Ala ERR $\gamma$ . Wild-type ERR $\gamma$  considerably increased the promoter activity which was further augmented in presence of OGT, whereas OGA co-expression greatly impaired ERR $\gamma$  effect. While at the same time, Ser317Ala+Ser319Ala ERR $\gamma$  could not greatly activate the promoter (Figure 5D). Next, ChIP assay was performed in MPH to monitor the effect of HBP inhibition on ERR $\gamma$  recruitment to the endogenous PEPCK gene promoter. Under basal conditions, ERR $\gamma$  occupied the PEPCK promoter. However, GlcN

treatment significantly augmented  $ERR\gamma$  occupancy on the PEPCK promoter, whereas HBP inhibition by DON treatment markedly diminished the occupancy. We also observed a similar binding pattern of PGC-1 $\alpha$  (Figure 5E). Together, these results demonstrate that *O*-GlcNAcylation by HBP governs gluconeogenic activity of  $ERR\gamma$ .

### **$ERR\gamma$ *O*-GlcNAcylation is required for hepatic gluconeogenesis**

Diabetic conditions induce  $ERR\gamma$  gene expression and promote gluconeogenesis [18]. Hence, we speculated that  $ERR\gamma$  could be *O*-GlcNAcylated under diabetic conditions. As we expected, *O*-GlcNAcylation of  $ERR\gamma$  was greatly increased in HFD fed, *ob/ob* and *db/db* mice (Figure 6A-B). Previously it was reported that diabetic conditions promoted OGT gene expression [7]. We also noticed a significant increase in OGT mRNA levels in HFD-induced diabetic mouse, although, OGA mRNA levels were also elevated (Supplementary figure 4F). Overexpression of  $ERR\gamma$  promotes hepatic gluconeogenesis and elevates blood sugar levels [28], [18]. Therefore we compared the effect of wild-type and Ser317Ala+Ser319Ala  $ERR\gamma$  overexpression in mouse liver. In accordance with previous results, glucose excursion during intraperitoneal glucose tolerance test (IPGTT) was significantly higher in Ad-wild-type  $ERR\gamma$ -injected mice compared to control mice, but Ad-Ser317Ala+Ser319Ala  $ERR\gamma$ -injected mice showed normal blood glucose levels (Figure 6C). Fasting blood glucose levels and PEPCK and G6Pase mRNA levels were significantly higher for Ad-wild-type  $ERR\gamma$ -infection compared to Ad-Ser317Ala+Ser319Ala  $ERR\gamma$  (Figure 6D). Effectiveness of  $ERR\gamma$  overexpression was confirmed by western blot analyses (Supplementary figure 4G). Next, to negate the effect of *O*-GlcNAcylation we overexpressed OGA in mouse liver. Disrupting *O*-GlcNAcylation of  $ERR\gamma$  in mice infected with Ad-wild-type  $ERR\gamma$  through overexpression of hepatic OGA by Ad-OGA

greatly lowered the gluconeogenic profile (Figure 6E). Effectiveness of ERR $\gamma$  overexpression was confirmed by western blot analyses (Supplementary figure 4H). Finally, on the basis of the previous result (Figure 6C-D), we performed *in vivo* imaging analysis to verify the effect of *O*-GlcNAcylation of ERR $\gamma$  on hepatic gluconeogenesis at the transcriptional levels. Ad-wild-type ERR $\gamma$ -dependent induction of PEPCK promoter activity was significantly reduced in mice injected with Ad-Ser317Ala+Ser319Ala ERR $\gamma$  (Figure 6F). Overall, these results suggest that *O*-GlcNAcylation is prerequisite for ERR $\gamma$  to trigger hepatic gluconeogenesis.

## DISCUSSION

Several transcription factors promote gluconeogenesis in the fasted state and type 2 diabetes. We hypothesize that in the fasting and diabetic states gluconeogenesis generates fructose-6-phosphate, which is utilized by HBP to *O*-GlcNAcylate transcription factors and co-activators to further promote gluconeogenesis. In the current study, we show that ERR $\gamma$  is stabilized by *O*-GlcNAcylation in the fasted and diabetic states to promote gluconeogenic gene induction. Hence, we suggest a positive feed-forward loop in which glucose entry into the HBP promotes gluconeogenesis in the fasting and diabetic conditions in the liver.

Glucagon-insulin crosstalk regulates ERR $\gamma$  protein stability and transcriptional activity [28], [20]. Herein, we investigated whether ERR $\gamma$  protein stability and transcriptional activity is influenced by *O*-GlcNAcylation. In fact, glucagon stabilized ERR $\gamma$  by promoting its *O*-GlcNAcylation (Figure 2D-F). *O*-GlcNAcylation can increase protein stability and transcriptional activity by inhibiting ubiquitination or promoting deubiquitination [30], [31], [33]. It can also reduce protein stability and transcriptional activity by increasing ubiquitination [36], [37]. However, we observed that *O*-GlcNAcylation stabilized ERR $\gamma$  protein by inhibiting its ubiquitination (Figure 2D-F). Our results clearly demonstrated that incremental *O*-GlcNAcylation mediated reduction in ubiquitination was a result of greater inhibition of the interaction between ERR $\gamma$  and E3 ubiquitin ligase Mdm2 that resulted in increased protein stability (Figure 2C). Phosphorylation of GFAT1 by cAMP-dependent protein kinase blocks its enzyme activity [38], whereas phosphorylation of GFAT2 by cAMP-dependent protein kinase increases its enzyme activity [39]. Our observation that glucagon robustly enhances *O*-GlcNAcylation of ERR $\gamma$  and insulin inhibits it (Figure 2F) could be due to GFAT2 activation. *O*-

GlcNAcylation can affect transcription factors by modifying key residues involved in their interaction with co-activators [40]. It can also induce important conformational changes within transcription factors, which might have a direct impact on their activity, as demonstrated for the estrogen receptor [41]. Three dimensional structural features of ERR $\gamma$  also suggest that *O*-GlcNAcylation may trigger a conformational change of ERR $\gamma$ -LBD that contains the AF-2 domain (Figure 3D). This probable conformational change may be crucial for inhibition of ubiquitination and ERR $\gamma$ -PGC-1 $\alpha$  interaction. Perhaps, S317A ERR $\gamma$  and S319A ERR $\gamma$ , in spite of being partially *O*-GlcNAcylated, were heavily ubiquitinated (Figure 3E) and were unable to interact with PGC-1 $\alpha$  (Supplementary figure 4C). The two single mutants may not attain the desired conformational change required to inhibit ubiquitination and interact with co-activator PGC-1 $\alpha$  due to incomplete *O*-GlcNAcylation. Further investigation is required to confirm whether *O*-GlcNAcylation influences ERR $\gamma$ -LBD structure. Previously Yang et al. reported that the transcripts of ERR $\gamma$  followed a cyclic pattern in its diurnal rhythmicity in the liver [42]. ERR $\gamma$  transcripts reach maximum levels in the liver during the day time. The observed result of *O*-GlcNAcylation mediated stability of ERR $\gamma$  may have been influenced by the diurnal rhythmicity in the liver.

*O*-GlcNAcylation takes place in response to high glucose or insulin [43], [31], [44]. PGC-1 $\alpha$  and CRTC2 undergo *O*-GlcNAcylation in hyperglycemic and hyperinsulinemic diabetic mouse [30], [7]. Interestingly, low glucose conditions also promote *O*-GlcNAcylation [30], [7], [9]. Glucose deprivation induces protein *O*-GlcNAcylation and OGT expression as well [45]. All these reports suggest that both high and low glucose conditions promote *O*-GlcNAcylation *in vitro* and *in vivo*. Glucose in the form of fructose-6-phosphate is utilized by hexosamine

biosynthetic pathway to *O*-GlcNAcylate proteins under different conditions. In the fed conditions, high circulating glucose could be converted to fructose-6-phosphate and utilized in *O*-GlcNAcylation. Although the circulating glucose concentration is high in the diabetic condition, the diabetic condition differs from the fed condition in that the activity of glucokinase, which converts glucose to glucose-6-phosphate, is low in the liver [46], [47], [48]. Therefore, circulating glucose is less readily converted to fructose-6-phosphate in the diabetic condition. In the diabetic conditions hepatic gluconeogenesis is significantly upregulated [49], producing fructose-6-phosphate, which could be utilized in *O*-GlcNAcylation. Furthermore, in low circulating glucose (fasting) conditions, glycogenolysis and gluconeogenesis are both called into play to maintain blood glucose levels. During early fasting glycogenolysis, stimulated by glucagon, produces glucose-6-phosphate which is in equilibrium with fructose-6-phosphate [50]. Therefore, glycogenolysis, especially during early fasting, is surely a major source of fructose-6-phosphate. During short-term fasting, glucagon also triggers the initial induction of hepatic gluconeogenesis through activation of CREB-CRTC2 [7]. In prolonged fasting, PGC-1 $\alpha$ , FOXO1 and ERR $\gamma$  promote hepatic gluconeogenesis [30], [51], [28]. During that initial induction period (short-term fasting), hepatic glycogenolysis and gluconeogenesis produce fructose-6-phosphate which might be utilized to *O*-GlcNAcylate ERR $\gamma$  to further promote gluconeogenesis during prolonged fasting. We observed that blood glucose levels were decreased during fasting in a time dependent manner, whereas serum glucagon levels and ERR $\gamma$  *O*-GlcNAcylation levels were steadily increased (Supplementary figure 1E-F), indicating that circulating glucagon levels are more important than circulating glucose levels for *O*-GlcNAcylation of ERR $\gamma$  in fasting. Moreover, OGT mRNA levels were significantly enhanced in response to fasting, even though OGA mRNA levels were also enhanced but it was less

significant compared to OGT (Supplementary figure 1D). Enhanced OGT mRNA levels could also be responsible for fasting dependent O-GlcNAcylation of ERR $\gamma$ .

Conserved ERR $\gamma$  response element (ERRE) on the PEPCK promoter is required for the transcription of that gene in response to fasting and diabetes mediated gluconeogenesis [28], [18], hence we explored the role of ERR $\gamma$  in HBP mediated gluconeogenesis. Loss of endogenous ERR $\gamma$  in primary hepatocytes led to a significant decrease in HBP-induced gluconeogenic profile (Figure 5), implying the importance of O-GlcNAcylation of ERR $\gamma$  in the context of gluconeogenesis. Diabetic conditions promote O-GlcNAcylation mediated gluconeogenesis in the diabetic mice [7], [30]. As a matter of fact, ERR $\gamma$  was highly O-GlcNAcylated in diabetic mice (Figure 6A-B). Hepatic overexpression of wild-type ERR $\gamma$  caused glucose intolerance with hyperglycaemia, whereas O-GlcNAcylation mutant ERR $\gamma$  overexpression showed glucose tolerance with euglycaemia in mice (Figure 6C-D). O-GlcNAcylation was blocked by using either OGT or GFAT inhibitor or by enzymatically modulating OGA or OGT expression to investigate the effect of their inhibition on glycemia in diabetic mice. The OGT inhibitor alloxan was used in many studies [52], [53], [54], but it has wide off-target effects and general cellular toxicity [55]. Another OGT inhibitor Ac<sub>4</sub>-5S-GlcNAc was used in wide range of studies [56], [57], [58], but it affects other glycosyltransferase and impairs N-glycosylation and extracellular glycan synthesis in cultured cell lines [59]. Moreover, the enzymatic approach modulating OGA or OGT expression was successfully utilized to restore glucose homeostasis. Overexpression of hepatic OGA or knockdown of hepatic OGT inhibited aberrant gluconeogenesis and significantly improved glycemic conditions in diabetic mice [7], [30], [31]. We observed that disruption of O-

GlcNAcylation by hepatic OGA overexpression reduced gluconeogenic profile in normal mice expressing Ad-ERR $\gamma$  (Figure 6E), unambiguously illustrating that *O*-GlcNAcylation is prerequisite for gluconeogenic function of ERR $\gamma$ .

We conclude that the fasting and diabetic conditions promote *O*-GlcNAcylation of ERR $\gamma$ . *O*-GlcNAcylation is imperative for ERR $\gamma$  protein stability, and enhances gluconeogenic activity of ERR $\gamma$ . The fed state, however, reduces *O*-GlcNAcylation of ERR $\gamma$ , resulting in ubiquitin-mediated degradation of ERR $\gamma$  (Figure 6G). Our results indicate a vital role for *O*-GlcNAcylation of ERR $\gamma$  in maintaining normal glucose levels during fasting and also in mediating the elevated blood glucose levels in type 2 diabetes. Hence, pharmacological inhibition of *O*-GlcNAcylation mediated hyper-activation of ERR $\gamma$  might provide a pathway for preventing hyperglycaemia and treating type2 diabetes.

## ACKNOWLEDGEMENTS

We would like to thank David Moore (Baylor College of Medicine, Houston, TX, USA) and Seok-Yong Choi (Department of Biomedical Sciences, Chonnam National University Medical School, Gwangju, Republic of Korea) for helpful discussion and Ji Min Lee, Yong Soo Lee, Ki Sun Kim, Soon-Young Na, Yaochen Zhang for technical assistance. This work was supported by National Creative Research Initiatives Grant (20110018305) through the National Research Foundation of Korea (NRF) funded by the Korean government (Ministry of Science, ICT & Future Planning) to HSC. This research was supported by the NRF funded by the Ministry of Education, Science and Technology (NRF-2013R1A2A1A01008067 and NRF-2015M3A9B6073840) to JWC.

The authors declare that they have no conflict of interest.

JM and HSC conceived and designed research; JM performed experiments; YHK performed mouse *in vivo* imaging; HBK, BGK and SHK performed LC-MS/MS CID site mapping analysis for identification of *O*-GlcNAcylation sites; JM, HSC, JSK, JWC, IKL, SHK, CHL, RAH analyzed the data; DKK, YSJ, EKY, JWC provided reagents/materials/ analysis tools; JM, HSC Wrote the paper. Professor Hueng-Sik Choi is the guarantor of this work and, as such, had full access to all the data in the study and takes responsibility for the integrity of the data and for the accuracy of the data analysis.

**FIGURE LEGENDS**

**Figure 1. ERR $\gamma$  is modified by O-GlcNAcylation.** (A) Mouse primary hepatocytes were treated with GlcN in a dose dependent manner for 6 h and subsequently immunoprecipitated with ERR $\gamma$  antibody. Total proteins were analyzed for the O-GlcNAcylation by immunoblot with O-GlcNAc, OGT, ERR $\gamma$  and  $\alpha$ -tubulin antibodies. (B) Mouse primary hepatocytes were incubated in 5 mM or 25 mM glucose media overnight followed by immunoprecipitation with ERR $\gamma$  antibody and immunoblot with O-GlcNAc, ERR $\gamma$  and  $\alpha$ -tubulin antibodies. (C, D) HEK 293T cells were transfected with expression vector for HA-ERR $\gamma$  (C) and HA-ERR $\alpha$  (D) alone or with expression vector for FLAG-OGT, followed by immunoprecipitation with HA antibody and immunoblot with O-GlcNAc, HA and  $\alpha$ -tubulin antibodies. (E) HEK 293T cells transfected with plasmids encoding HA-ERR $\gamma$  and FLAG-OGA or FLAG-OGT. At 24 h after transfection cells were treated with MG-132 (10 $\mu$ M) for 6 h followed by immunoprecipitation with HA antibody and immunoblot with O-GlcNAc, ubiquitin (Ub), HA and  $\alpha$ -tubulin antibodies. (F) HEK 293T cells were transfected with Sft4-luc along with the indicated plasmids. (G) HEK 293T cells were transfected with Gal4-tk-luc along with the indicated plasmids. \*p <0.05, and \*\*P <0.005 using Student's t-test. Error bars show  $\pm$  s.e.m.

**Figure 2. Glucagon increases O-GlcNAcylation of ERR $\gamma$ .** (A) C57BL/6 mice (n=5) were fasted for 6 h and refed for 2 h, followed by liver tissue isolation. Immunoprecipitation with ERR $\gamma$  antibody and immunoblot with O-GlcNAc, Ub, ERR $\gamma$  and  $\alpha$ -tubulin antibodies were performed. All of the samples were combined for western blot analyses. (B) Ad-green fluorescent protein (GFP) or Ad-OGA was administered via tail-vein injection into C57BL/6 mice (n=6). At day 6 after injection, mice were fasted for 6 h and sacrificed. Liver tissue from

mice was homogenized for immunoprecipitation with ERR $\gamma$  antibody and immunoblot with *O*-GlcNAc, Ub, ERR $\gamma$  and  $\alpha$ -tubulin antibodies. All of the samples were combined for western blot analyses. (C) Liver tissue from C57BL/6 mice (n=5) fasted for different time points as indicated, was homogenized for immunoprecipitation with ERR $\gamma$  antibody and immunoblot with *O*-GlcNAc, OGT, Mdm2, ERR $\gamma$  and  $\alpha$ -tubulin antibodies. All of the samples were combined for western blot analyses. (D) AML12 cells were transfected with FLAG-ERR $\gamma$ . At 24 h post transfection, cells were incubated with vehicle or glucagon (100 nM) for different time points as indicated. Immunoprecipitation with FLAG antibody and immunoblot with *O*-GlcNAc, Ub, FLAG and  $\alpha$ -tubulin antibodies were performed. (E) AML12 cells were transfected with FLAG-ERR $\gamma$ . At 24 h post transfection, cells were infected with Ad-GFP or Ad-OGA as indicated. At 24 h post infection, cells were incubated with glucagon (100 nM) for 6 h followed by immunoprecipitation with FLAG antibody and immunoblot with *O*-GlcNAc, Ub, FLAG and  $\alpha$ -tubulin antibodies were performed. (F) AML12 cells were transfected with FLAG-ERR $\gamma$ . At 24 h post transfection, cells were incubated with glucagon (100 nM) for 6 h or glucagon (100 nM) for 6 h followed by insulin (100 nM) for 6 h. Immunoprecipitation with FLAG antibody and immunoblot with *O*-GlcNAc, OGT, Ub, FLAG and  $\alpha$ -tubulin antibodies were performed.

**Figure 3. ERR $\gamma$  is modified by *O*-GlcNAcylation at Ser317 and Ser319.** (A) C57BL/6 mice (n=5) were injected via tail veins with adenoviral vector expressing FLAG-ERR $\gamma$ . Six days later, mice were fasted for 6 h and liver extracts were prepared. The FLAG-ERR $\gamma$  was purified using Anti-FLAG M2 agarose. (B) Proteins were separated using SDS-PAGE and stained by colloidal Coomassie blue. (C) Schematic diagram of ERR $\gamma$  structure (amino acids, 1–458). ERR $\gamma$  consists of N-terminal domain, DNA-binding domain (DBD), hinge domain, Ligand-binding

domain (LBD) and C-terminal domain.  $ERR\gamma$  is *O*-GlcNAcylated at S317 and S319. The amino acid sequences of ERR family members,  $ERR\alpha$ ,  $ERR\beta$ , and  $ERR\gamma$  are given below. (D) Two serine residues of  $ERR\gamma$ -LBD. Twelve LBD structures (PDB IDs 2ewp, 2gpp, 2gp7, and 2p7z) were superimposed, which showed root-mean-square deviation values of less than 0.4 Å for all the aligned residues.  $ERR\gamma$ -AF-2 domain is represented as an orange color surface;  $ERR\gamma$ -LBD as a grey-colored surface with two serine residues in space-filling models in the left and below-right panels. On the upper-right panel, the superimposed  $ERR\gamma$ -LBD structures are displayed with ribbons and differentiated by colors; two serine residues are drawn as stick models. (E) AML12 cells were transfected with plasmids encoding FLAG-wt  $ERR\gamma$ , FLAG-Ser317Ala  $ERR\gamma$ , FLAG-Ser319Ala  $ERR\gamma$  and FLAG-Ser317Ala+Ser319Ala  $ERR\gamma$ . At 24 h after transfection cells were treated with GlcN (10 mM) for 6 h and MG-132 (10  $\mu$ M) for 6 h followed by immunoprecipitation with FLAG antibody and immunoblot with *O*-GlcNAc, Ub, FLAG and  $\alpha$ -tubulin antibodies. (F) AML12 cells transfected with FLAG-wt  $ERR\gamma$ , FLAG-S317A  $ERR\gamma$ , FLAG-S319A  $ERR\gamma$  and FLAG-S317A+S319A  $ERR\gamma$  were metabolically labeled for 30 min followed by chase for the indicated times. FLAG- $ERR\gamma$  was immunoprecipitated with M2 antibody and detected by autoradiography. (G)  $ERR\gamma$ -dependent activation of the Sft4-luc. Transient transfection was performed in HEK 293T cells with the indicated plasmid DNAs. (H) ChIP assay showing the occupancy of wild-type  $ERR\gamma$ , S317A  $ERR\gamma$ , S319A  $ERR\gamma$  and S317A+S319A  $ERR\gamma$  on ERRE1 of PEPCK1 promoter from DMSO and GlcN-treated AML12 cells. \*\*\* $P < 0.0005$  using Student's t-test. Error bars show  $\pm$  s.e.m.

**Figure 4. *O*-GlcNAcylation affects  $ERR\gamma$ -PGC-1 $\alpha$  interaction but not  $ERR\gamma$  cellular localization.** (A) Immunocytochemistry showing subcellular localization of wild-type and

mutant ERR $\gamma$  in AML12. The cells were transfected with plasmids expressing FLAG-wt ERR $\gamma$  and FLAG-Ser317Ala+Ser319Ala ERR $\gamma$ . At 24 h after transfection cells were fixed, immunostained and observed by confocal microscopy. (B) AML12 cells were transfected with plasmids encoding FLAG-wt ERR $\gamma$  and FLAG-Ser317Ala+Ser319Ala ERR $\gamma$ . At 24 h after transfection cells were treated with MG-132 (10  $\mu$ M) and DMSO or GlcN (10 mM) or DON (40  $\mu$ M) for 6 h followed by immunoprecipitation with FLAG antibody and immunoblot with *O*-GlcNAc, PGC-1 $\alpha$ , FLAG, and  $\alpha$ -tubulin antibodies. (C) AML12 cells were transfected with plasmids encoding FLAG-wt ERR $\gamma$  and HA-PGC-1 $\alpha$ . At 24 h after transfection cells were treated with DMSO or OGA inhibitor STZ (5 mM) for 6 h followed by immunoprecipitation with HA antibody and immunoblot with FLAG, HA and  $\alpha$ -tubulin antibodies. (D) HEK 293T cells were transfected with plasmids encoding Gal4-wt ERR $\gamma$ -LBD, Gal4-Ser317Ala+Ser319Ala ERR $\gamma$ -LBD and HA-PGC-1 $\alpha$ . At 24 h post transfection immunoprecipitation with HA antibody and immunoblot with Gal4 and HA antibodies were performed. (E) HEK 293T cells were transfected with Gal4-tk-luc along with the indicated plasmids. \* $p < 0.05$  using Student's t-test. Error bars show  $\pm$  s.e.m.

**Figure 5. *O*-GlcNAcylation regulates ERR $\gamma$  transcriptional activity.** (A) Effect of ERR $\gamma$  knockdown on GlcN-induced gluconeogenic genes in mouse primary hepatocytes. Hepatocytes were infected with Ad-US or Ad-shERR $\gamma$ . At 48 h post infection, cells were treated with DMSO or GlcN (10 mM) for 6 h followed by immunoblot with PEPCK, G6Pase, ERR $\gamma$  and  $\alpha$ -tubulin antibodies. (B) Effect of ERR $\gamma$  knockdown on basal and OGT-induced gluconeogenic genes in mouse primary hepatocytes. Glucose output assay was performed in mouse primary hepatocytes. (C) Effect of Glc and GlcN on wild-type (wt) and ERR $\gamma$  binding site (ERRE)

mutant PEPCK-luc. HEK 293T cells were transfected with indicated plasmids followed by Glc or GlcN treatment. (D) *O*-GlcNAcylation-dependent activation of the PEPCK1-luc by ERR $\gamma$ . HEK 293T cells were transfected with indicated plasmids. (E) CHIP assay showing the occupancy of ERR $\gamma$  on ERRE1 of PEPCK1 promoter from GlcN, DON-treated mouse primary hepatocytes. \* $p < 0.05$ , and \*\* $P < 0.005$  using Student's t-test. Error bars show  $\pm$  s.e.m.

**Figure 6. ERR $\gamma$  *O*-GlcNAcylation required for hepatic gluconeogenesis.** (A-B) *O*-GlcNAcylation of ERR $\gamma$  in diabetic conditions, ERR $\gamma$  was immunoprecipitated with ERR $\gamma$  antibody followed by immunoblot with *O*-GlcNAc, ERR $\gamma$ , PEPCK and  $\alpha$ -tubulin antibodies from liver tissue of C57BL/6 mice (n=3) fed with normal chow diet (NCD) and high fat diet (HFD) (A), from wild-type, *ob/ob* and *db/db* mice (n=3) (B). (C) Ad-GFP, Ad-wt ERR $\gamma$  or Ad-Ser317Ala+Ser319Ala ERR $\gamma$  were administered via tail-vein injection into C57BL/6 mice (n=5). Glucose tolerance test at day 5 after injection. Glucose was measured at the indicated times after 1 g/kg intraperitoneal glucose injection. (D) (Left panel) 4 h fasting blood glucose levels in C57BL/6 mice (n=5) at day 6 after Ad-GFP, Ad-wt ERR $\gamma$  or Ad-Ser317Ala+Ser319Ala ERR $\gamma$  injection. (Middle and right panel) qPCR analyses of total RNA isolated from liver at day 7 after injection. (E) (Left panel) 4 h fasting blood glucose levels in C57BL/6 mice (n=5) at day 6 after Ad-GFP, Ad-ERR $\gamma$  or Ad-ERR $\gamma$  + Ad-OGA injection. (Middle and right panel) qPCR analyses of total RNA isolated from mice liver at day 7 after injection. (F) (Left) *In vivo* imaging of hepatic PEPCK1-luciferase (Ad-PEPCK1-luc) activity in presence of Ad-GFP or Ad-wt ERR $\gamma$  or Ad-Ser317Ala+Ser319Ala ERR $\gamma$  in fasted (16 h) C57BL/6 mice (n=3). (Right) Quantitation of luciferase activity is also shown. (G) Schematic representation of the proposed model that the fasting and diabetic conditions promote *O*-GlcNAcylation of ERR $\gamma$ . *O*-GlcNAcylation is

imperative for ERR $\gamma$  protein stability, and enhances gluconeogenic activity of ERR $\gamma$ . Fed state, however, reduces *O*-GlcNAcylation of ERR $\gamma$ , resulting in ubiquitin-mediated degradation of ERR $\gamma$ . \**p* <0.05, \*\**P* <0.005, and \*\*\**P* <0.0005 using Student's *t*-test. Error bars show  $\pm$  s.e.m.

## FIGURE LEGENDS

**Supplementary Figure 1.** *O*-GlcNAcylation is affected by both glucosamine and high glucose levels. (A) AML12 cells were treated with DMSO or GlcN (10 mM) for 6 h as indicated. Immunoprecipitation with ERR $\gamma$  antibody and western blot analyses with Ub, ERR $\gamma$  and  $\alpha$ -tubulin antibodies were performed. (B) HEK 293T cells were transfected with Sft4-luc along with the indicated plasmids followed by GlcN (10 mM) treatment for 6 h. (C) Liver tissue from C57BL/6 mice (n=5) fasted for different time points as indicated, was homogenized for immunoprecipitation with ERR $\gamma$  antibody and immunoblot with OGT, OGA and  $\alpha$ -tubulin antibodies. All of the samples were combined for western blot analyses. (D) Liver tissue from C57BL/6 mice (n=5) fasted for different time points as indicated, was homogenized for RNA isolation and qPCR analyses of total RNA. (E) Fasting blood glucose levels in C57BL/6 mice (n=5). (F) Fasting blood glucagon levels in C57BL/6 mice (n=5). (G) AML12 cells were incubated in 5 mM or 25 mM glucose media overnight followed by glucagon (100 nM) treatment for 6 h. Immunoprecipitation with ERR $\gamma$  antibody and western blot analyses with *O*-GlcNAc, ERR $\gamma$  and  $\alpha$ -tubulin antibodies were performed as indicated. (H) AML12 cell were treated with GlcN or different doses of glucose for 6 h followed by ERR $\gamma$  mRNA measurement by qPCR. NS, not significant. \* $p < 0.05$ , \*\* $p < 0.005$  and \*\*\* $p < 0.0005$  using Student's t-test. Error bars show  $\pm$  s.e.m.

**Supplementary Figure 4.** O-GlcNAcylation affects ERR $\gamma$  protein stability and activity. (A) HEK 293T cells were transfected with plasmids encoding FLAG-wt ERR $\gamma$ , FLAG-Ser317Ala ERR $\gamma$ , FLAG-Ser319Ala ERR $\gamma$  and FLAG-Ser317Ala+Ser319Ala ERR $\gamma$ . At 24 h after transfection cells were treated with cycloheximide (CHX) (10 mg/mL) for the indicated times and FLAG-ERR $\gamma$  levels were detected by immunoblot using FLAG and  $\alpha$ -tubulin antibodies. (B) AML12 cell were treated with DMSO or GlcN or DON for 6 h followed by PGC-1 $\alpha$  mRNA measurement by qPCR. NS, not significant. (C) HEK 293T cells were transfected with plasmids encoding FLAG-wt ERR $\gamma$ , FLAG-Ser317Ala ERR $\gamma$ , FLAG-Ser319Ala ERR $\gamma$ , FLAG-Ser317Ala+Ser319Ala ERR $\gamma$  and HA-PGC-1 $\alpha$ . At 24 h post transfection cells were treated with MG-132 (10  $\mu$ M) for 6 h followed by immunoprecipitation with HA antibody and immunoblot with FLAG, HA and  $\alpha$ -tubulin antibodies. (D) HEK 293T cells were transfected with Gal4-tk-luc along with the indicated plasmids followed by GlcN (10 mM) treatment for 6 h. (E) Effectiveness of OGT overexpression was confirmed by western blot analyses. Mouse Primary hepatocytes were first infected with Ad-US or Ad-shERR $\gamma$  followed by Ad-GFP or Ad-OGT infection as indicated. Total proteins were analyzed for the FLAG expression by immunoblot. (F) Liver tissue of C57BL/6 mice (n=3) fed with NCD or HFD was homogenized for RNA isolation and qPCR analyses of total RNA. (G) Effectiveness of ERR $\gamma$  overexpression was confirmed by western blot analyses. Ad-GFP, Ad-wt ERR $\gamma$  or Ad-Ser317Ala+Ser319Ala ERR $\gamma$  was administered via tail-vein injection into C57BL/6 mice (n=5). Total proteins were isolated at day 7 after injection and analyzed for the FLAG expression by immunoblot. (H) Effect of OGA overexpression on ERR $\gamma$  was examined by western blot analyses. Ad-GFP, Ad-wt ERR $\gamma$  or Ad-wt ERR $\gamma$  +Ad-OGA was administered via tail-vein injection into C57BL/6 mice (n=5). Total proteins were isolated at day 7 after injection and analyzed for ERR $\gamma$  expression by immunoblot. \*p <0.05, \*\*P <0.005 and \*\*\*<0.0005 using Student's t-test. Error bars show  $\pm$  s.e.m.
